Art. II.-Further Additions to our Knowledge of the New Zealand Crustacea. By Charles Chilton, M.A.
[Read before the Philosophical Institute of Canterbury, 7th September, 1882.]

> Plates I.-III.
> BRACHYURA.

Hymenosoma lacustris. Elamena (?) lacustris, Chilton. (Trans. N.Z. Inst., vol. xiv., p. 172.)
This species was described from a single specimen, a female. I have since, through the kindness of Professor Hutton, received seven others, all males, so that I am now able to describe it more fully and to refer it to its proper genus.

In the Catalogue of the Stalk- and Sessile-eyed Crustacea of Australia Mr. Haswell has replaced the genera Hymenicus and Halicarcinus by Leach's original genus Hymenosoma; and my species will also come under this genus as it is defined in Mr. Haswell's catalogue. Its name will therefore be Hymenosoma lacustris.

Specific description :-Carapace nearly circular, rather broader than long ; flat, naked, or with a few scattered hairs. Rostrum broad, strongly depressed, its upper surface concave from side to side, extremity in the form of an obtuse angle. Antero-lateral margins of the carapace with two obscure teeth. Chelæ of male small, propodos only slightly broader than the carpus, hairy. Ambulatory legs somewhat densely covered with long hairs, tarsi long, slender, compressed, densely-haired. Last pair of legs somewhat shorter than the preceding. Abdomen of male of five joints subequal in length, third rather narrower than the first and second, fourth nearly as wide as the third, last broadly rounded at the end; margin fringed with very short hairs, some longer ones being scattered on the surface. Abdomen of female with a slight median ridge along its whole length.

Hab. Lake Pupuke. (Fresh water.)
The hairs on the legs and carapace appear to be somewhat variable.
The third (external) maxillipedes are shown in pl. I., fig. $2 a$. On them are found setæ of several kinds ranging from the ordinary plumose setæ (c) to others strongly serrated on each side (b).

This species is remarkably near Hymenosoma australe, Haswell, from Port Phillip. From this, however, it differs in the chelæ of the male which are small, while in H. australe they are " extremely large."

ISOPODA.
Genus Scutuloidea, (novum).
Generic description :-Body not very convex. Pereion much broader than the cephalon, increasing regularly in breadth up to the fourth segment and then decreasing again.

Pleon with last segment large and triangular, emarginate at apex. Last pair of pleopoda single-branched, consisting of a single broad squamiform plate.

This genus I have made for an Isopod of which I took several specimens at Timaru, and since then at Lyttelton Harbour. It will, I think, come nearest to Cassidina, Milne-Edwards; however, it does not resemble C.typa so much as it does C. latistylis, Dana,* the figure of which I have been able to see through the kindness of Professor J. von Haast. According to Mr. Miers, C. latistylis is the same as C. emarginata, Guérin-Ménev., and is found at Kerguelen's Island. $\dagger$

From Cassidina, however, my genus differs in having the last pair of pleopoda unibranched. In Cassidina the outer branch is present, but is almost rudimentary, while the inner and basal one is large and broad; so that Cassidina appears to be truly intermediate between Scutuloidea and some genus such as Zuzara, which has the two branches equally developed. Scutuloidea maculata, sp. nov. Pl. I., fig. 1.

Head moderately large, transverse, about twice as broad as long, produced obtusely between the bases of the antennæ. First thoracic leg short and stout, second long and slender, the rest more like the first though not quite so stout, all having the propodos ending in two strongly curved claws. Segments of pereion subequal in length. Pleon of two segments, last large, triangular, with a wide shallow notch at apex. Last pair of pleopoda each consisting of a single broad squamiform plate, more than twice as long as broad, narrowing posteriorly, the inner edge conterminous with the side of the last segment of the pleon, and reaching very nearly to the end of pleon.

Colour-pale yellowish-brown, whole body thickly covered with small purple spots.

Length about $\frac{1}{6}$ of an inch.
Hab. Timaru, among seaweed at north side of the breakwater; Lyttelton Harbour.

Additional remarks on structure :-
The eyes are moderately large and placed wide apart at the posterolateral angles of the head.

The upper antenua (fig. $1 a$ ) is considerably shorter than the lower ; the three joints of the peduncle decrease in size distally and pass insensibly into the flagellum, which consists of but few joints. On the distal portion of it "sensory setæ" are found. These at first appear to be egg-cup shaped bodies, having a stout base from which arises all round a curved portion forming the cup. But careful focussing will show that there is

[^0]$\dagger$ Trans. Royal Society, vol. 168 (extra volume), p. 204.
another portion stretching out of the part already described, like a greatly elongated egg; this portion is exceedingly delicate and transparent; the small dot which marks the end of it is often more easily seen than the rest. (Fig. 1b.)

The mandible bears a three-jointed appendage; the first and second joints being equal in length and longer than the third; the last two bearing stout setæ which increase in length as they approach the distal ends of the joints on which they are situated (fig. 1c).

The first maxilla consists of two nearly straight lobes, the inner one tipped with slender plumose setæ, the outer one longer and larger and bearing strong serrated setæ at the extremity (fig. $1 d$ ).

The second maxilla consists of three delicate overlapping plates; the two outer ones of which bear similar long simple setæ which appear to be transversely ribbed (fig. $1 f$ ). On the third and inner lobe are setæ, two of which bear delicate filaments near the base only; the others bearing filaments on one side only throughout the whole length of the seta (fig. 1, $e, f, g)$.

The maxillipedes have the basal portion long and straight, tipped at the end with several moderately strong setæ. This basal portion bears a fourjointed appendage, the joints of which decrease in size distally; the first three have the distal end produced into a rounded lobe tipped with setæ. (Fig. 1 h.)

The first pair of legs (fig. $1 k$ ) is short and stout; the meros is short and expands greatly at the distal end, carpus very short, the dactylos is large and bears at the end two claws, the terminal one larger than the other which bears a small piece projecting on its inner side (fig. 1 l ). The large claw appears to be more or less articulated to the rest of the dactylos. The second leg (fig. 1 m ) is much longer and slenderer; the basos has its inner side fringed with short setæ, the meros is longer than in the first and expands distally, the carpus is slender and as long as the propodos; the dactylos ends with two claws (fig. $1 n$ ), the smaller with several stiff projections along its inner edge, one towards the base of the claw being much stouter than the others. The remaining legs are somewhat like the first, though not so stout, being thus more or less intermediate in form between the first and the second.

The pleopoda or branchial plates have the basal joint broad and supporting two large branchial plates, the inner one being longer than the outer and broader at the base than at the end; both abundantly supplied with long plumose setr (fig. 1 o ). The pleopoda all rest in a cavity formed by the excavation of the under side of the segments of the pleon, much in the same way as in Spheroma.

Genus Anthura, Leach. (Bate's and Westwood's Brit. Sessile-eyed Crust., vol. ii., p. 15̌7.)
Anthura affinis, sp. nov. Plate I., fig 4.
Segments of pereion subequal, cylindrical. Head somewhat shorter than the first segment of pereion. Antennæ short, not quite so long as the head; upper much smaller than the lower, consisting of four joints, of which the basal one is the largest, and a very small fifth joint bearing a small pencil of setæ; lower antennæ thick and strong, basal joint large, broad, with a groove above in which the upper antenua rests, the inner edge of this basal joint is straight and in close contact with that of the antenna on other side, along the median line ; basal joint followed by three subequal joints, and a short, thick, rudimentary flagellum, the joints of which bear setæ thickly set on one side.

First pair of legs very strong, not reaching beyond the head; basos very thick distally, ischios also thick and strong, meros short, carpus subtriangular, produced along the side of the propodos, and bearing setæ on its distal extremity; propodos thick, ovate, in contact with both meros and carpus, palm short with a strong projection against which the dactylos impinges ; dactylos short, strong, and curved. Remaining legs all similar, not subchelate, propodos longer than the carpus and meros together. First fire segments of the pleon united so closely that the lines of suture cannot be distinguished, sixth segment distinct bearing biramous appendages; outer ramus of a single joint, half as long as the inner, semicylindrical surromnding the inner ramus, its upper inner edge serrate and fringed with long setæ very delicately plumose; inner ramus of two joints equal in length and breadth, broad, edges fringed with long setæ; telson broad, round at end, with several long sete near the centre.

Colour-pale yellow with blotches of black on the head, segments of pereion, pleon and telson. Length about $\frac{1}{3}$ of an inch.

Hab. Lyttelton Harbour. Found on seaweed at low tide.
This species is a true Anthura, coming apparently near to $A$. gracilis, from which however it is sufficiently distinct.

The first pair of legs only are chelate, all the rest are simple; they have the dactylos large and strong, the end forming a claw distinct from the basal portion; at the base of this claw three or four simple setæ arise laterally, and a short stout one on the inside. There is also a short stout seta on the inner distal angle of the propodos (pl. I., fig. 4 c and d).

The pleopoda are of the usual form, having a short basal joint bearing two equal oval plates with the distal margins setose. Each of these branchial plates is slightly constricted on each side, half way between the two

TRANS.NZ.INSTTUUTE. VOL XV.PI.I.

ends. The first pair of pleopoda are modified so as to form an opereulum covering the others; one of the plates, the outer I think, is long and broad so that it extends along the whole of the under side of the pleon; the inner plate appears to perform no special function, it is small and narrow, apparently becoming rudimentary (fig. $4 f$ ). The setro on the pleopoda are long and fringed on each side with long plumes, which are exceedingly delicate.
Cubaris rugulosus, Miers. (Cat. Stalk- and Sessile-eyed Crustacea of N.Z., p. 96.)

This species was described by Mr. Miers from specimens in the collections of the British Museum. His specimens appear to have been imperfect, for he neither describes nor figures the antemæ. I have found it abundantly at Eyreton, and also in the bush at Oxford. The inner antennæ are very small and composed of three joints, the basal one stout, second short and narrowing distally, third about twice as long as the second, much narrower, with a few short setæ at the end (pl. I., fig. 3 a). The outer antennæ consist of seven joints. The basal one is short, the second and third subequal and rather shorter than the fourth; the fifth joint is the longest, and is longer than the flagellum, which consists of two joints, the first short, very slightly longer than broad, the second more than three times as long as the first and followed by a minute terminal joint which bears two or three short setæ ; the whole antenna, but more especially the distal portion, is finely hirsute, the hairs being short and delicate, much more so than can be shown in the figure (pl. I., fig. $3 b$ ).

In describing the last segment of the abdomen, Mr. Miers says: "terminal segment much the broadest at the base, with the sides at first converging and then parallel." In my specimens the sides after converging usually diverge slightly.

The colour varies considerably. It is usually yellowish-brown with darker patches, but some specimens are uniformly black.

Over the whole body the integument is covered with peculiar scale-like markings, each scale being usually more or less pointed at the end ( $\mathrm{pl} . \mathrm{I}$, fig. 3 c).
Philongria rosea, Koch. (Bate's and Westwood's Brit. Sessile-eyed Crust., vol. ii., p. 460.)
In a previous paper I have identified specimens found at Christchurch and Eyreton as this species, and at the same time adduced reasons for believing that it could not well have been introduced from Europe. Since then I have found specimens precisely similar in the bush at Oxford, so that I think there can be little doubt that it is really a native of New Zealand and has not been introduced.

I find that my specimens differ from those described by Messrs. Bate and Westrood in one small point, which I had previously overlooked. In theirs the upper surface of the body " is tuberculated, each tubercle emitting a minute seta at its top." In my specimens the tubercles are not very well marked, and the setr, though certainly very small, are perhaps rather too large to be called minute, as compared with the animal itself.

I do not, however, consider this difference sufficient to warrant its removal from the Ewropean species.

Genus Plakarthrium, (novum).
Body much depressed, almost flat. Both antennæ having some of the basal joints expanded, flat; outer antenna with a flagellum. Coxæ very largely developed. Last pair of pleopoda biramous, lamellar.
Plakarthrium typicum, sp. nov. Plate I., fig. 5.
First two joints of inner antenna much expanded, first sub-rectangular, second sub-triangular, bearing on its posterior border the third joint, which is small and not expanded and is followed by a very small joint bearing two or three auditory cilia. Outer antenna with peduncle of five joints ; the first two small and cylindrical, the third expanded, triangular, fourth expanded, transverse, fifth cylindrical, followed by a slender many-jointed flagellum reaching to the posterior border of the third thoracic segment. Eyes small, placed in the centres of the two rounded lateral portions of the head. Head transverse, about twice as broad as long, entirely enclosed by the expanded joints of the antennæ and by the coxæ of the first thoracic segment. Thoracic segments sub-equal in length, the central ones being rather broader than the first and the last. Coxæ very large, lamellar, more than half as broad as their segments ; coxa of last thoracic segment reaching nearly to the extremity of the last pair of pleopoda. First two pairs of legs slender, three following pairs short and stout, last two pairs slender, similar to the first two, all ending in strong curved claws. Abdomen sub-rectangular, showing indications of three segments, the last larger than the first two together; posterior border concave. Last pair of pleopoda apparently arising right at the posterior end of the abdomen, basal joint short, flat, about as long as broad, inner branch oblong, inner margin straight, outer branch broader, expanding distally.

Colour-light-reddish brown, with a few small scattered dots of a darker brown. Length about $\frac{1}{5}$ of an inch.

Hab. Lyttelton Harbour. On stems of a brown seaweed, probably L'cklonia radiata.

I do not know where this peculiar Isopod should be placed. In some respects it is like Anphoroidea, but it differs very greatly from it in others. As yet I have only found it on one kind of seaweed, probably Ecklonia
radiata. It affords a very good example of protective resemblance, for the body being very flat and of a brown colour can scarcely be distinguished from the seaweed, to which it closely adheres. It has several appliances which enable it to cling tightly to the seaweed; in the first place all the legs are furnished at the ends with powerful hooked claws, then on the under side of the basal joint of last pair of pleopoda and round the proximal edge of the outer branch are strong hooked setx, and besides this, on the basal joints of all the legs, on some parts of the under surface of the head and in one or two other places, are small projections of the integument which may possibly be hooked setæ, though their nature is not very apparent, but which certainly appear to lave the same function. They are shown on the basal joints of the legs in fig. $5 d$ and $f$.

In the mouth parts the maxillipedes appear to have the same form as in Spharoma, etc., consisting of a long slender basal portion bearing an appendage of four joints, none of which is produced into a lobe at the distal end. The maxillæ I have not made out satisfactorily. The mandible is long and slender and has a sharp cutting edge of four teeth, and below two setæ with stout bases. There is no appendage unless a rounded protuberance on the mandible itself is to be regarded as such (fig. $5 c$ ).

The branchial plates-pleopoda-rest in a slight hollow formed by the arching of the abdomen. There appear to be two distinct kinds, the first (fig. 5 g ) consists of a short basal joint bearing two long subequal joints, each of which bears several long plumose setre; in the second (fig. $5 h$ ) the basal joint is about twice as broad as long, the inner branch is short and triangular, the imner edge straight and the outer one slightly curved, it has no setæ except a few exceedingly delicate ones along the inner edge; the outer branch is of the same length as the inner, and is curved so as to fit alng the curved outer edge of the inner branch, it bears short plumose setr along its outer edge, these start about half-way along the joint, and are at first very small, but gradually increase in size till the end where they are largest.

When viewed from above the last pair of pleopoda appears to be articulated on to the abdomen at its posterior edge, but when seen from below it will be found that the basal joint extends anteriorly along the under side of the abdomen, and no doubt belongs as usual to the sixth segment of pleon, which is, together with the others, completely united to the terminal one or telson.

At the end of the abdomen, in the centre, there is a small opening formed by the posterior edge of the abdomen being slightly arched and thus raised a little above the inner branch of the last pleopod; at this opening is a kind of strainer formed by setæ on the posterior edge of the abdomen and
on the inner anterior angle of the inner joint of the last pair of pleopoda. Its function, doubtless, is to admit water to the branchial plates, and at the same time to prevent the ingress of sand or other extraneous matter, the flow of water is no doubt kept up by the movement of the branchial plates themselves.

All round the outer edge of the coxæ, the expanded joints of the antennæ and the last pair of pleopoda, two distinct parallel borders are to be seen, the outer part of the integument being apparently produced beyond the inner and more opaque parts. From the inner line numerous short setæ arise, these seldom reach much beyond the outer line. (See figs. $5 a, b, k$.)

Genus Limnoria, Leach.
(Bate's and Westwood's British Sessile-eyed Crustacea, vol. ii., p. 349.)
As this genus is new to New Zealand I quote here the generic characters.
"Oblong-ovate, depressed; antennæ subequal, cylindrical, not longer than the cephalon. Pereiopoda nearly alike, slender. Pleon six-jointed. Branchial plates naked. Terminal segment large, semicircular, with a lateral appendage on each side bearing two terminal slender styles."
Limnoria seynis, sp. nov. Pl. II., fig. 1.
Body covered with short setæ. Eyes large. Neither antenna longer than head, inner one stouter and longer than the outer, consisting of three joints, of which the second is the shortest, followed by a short flagellum of about three joints bearing setæ and long simple auditory cilia. Lower (outer) antennæ of four joints, the third and fourth subequal and longer than the first and second; followed by a short flagellum of three joints bearing simple setæ. Mandible strong, appendage small, apparently of only two joints, the last tipped with a few setæ. Maxillipedes similar to those of L. lignorum, but having the plate at base much longer, narrower at base than towards the distal end, extremity rounded, whole margin fringed with short setr. Terminal segment of the tail entire rounded and flattened, without central dorsal carina and with the margins not raised. Last pleopoda with the inner branch strong, about twice as long as broad, the end and onter margin supplied with setæ about as long as the joint; outer branch small pointed at the end, and with two or three setæ on the outer edge near the end.

Length- $\frac{1}{6}$ of an inch.
Colour-white, opaque.
Hab. On seaweed, Lyttelton Harbour.
This species is very near Limnoria lignorum, the dreaded "Gribble" of Europe, but it differs in several small points already mentioned. It also differs in habits; L. lignorum burrows into the wood of piers, piles, etc.; but L. segnis I found on the roots of Macrocystis. It is very sluggish and
does not move when taken out of the water, even if it is touched, and a good deal of extraneous matter is usually found among the short setæ which cover the body.

## AMPHIPODA.

## Genus Nicea.

(Cat. Amphip. Crus. Brit. Mus., p. 51.)
Nicea egregia, sp. nov. Plate II., fig. 2.
Female.-Body much compressed dorsally; each segment of pereion raised into a crest which projects backwards over the succeeding segment; first three segments of pleon produced dorsally into crests rather more prominent than those on the segments of pereion. Crest of first segment of pleon extending along the dorsal surface of the cephalon and rising abruptly therefrom. Eye moderately large, round. Cephalon produced slightly upwards at the base of the upper antenna. Upper antenna slorter than the lower, peduncle of three joints nearly equal in length, decreasing slightly in size distally; flagellum about as long as the peduncle, each joint bearing long auditory cilia on its under side at the distal end. Peduncle of lower antenna with three joints visible, last two equal in length and considerably longer than the first, flagellum longer than the peduncle, setæ in short tufts at the end of each joint. First and second gnathopoda equal in size and similar in form ; carpus long, sub-triangular, with setæ on its inner distal angle ; propodos oblong not broader than carpus, palm slightly oblique, defined by a stout tooth, hairy. Coxæ about as deep as their respective segments. Pereiopoda subequal rather stout; meros expanded distally and produced anteriorly in the first two, posteriorly in the last three pereiopoda, each pereiopod with dactylos long strong and curved with a short seta arising on the inner margin towards the end. All the pereiopoda nearly free from setæ. Of the last three pairs of pleopoda, the first two reach to the same point slightly beyond the extremity of the body; the rami are about equal in length to the peduncles, and are provided with short strong teeth at the extremity and on their upper margins. Last pair of pleopoda apparently rudimentary, consisting of two joints rounded and perfectly free from setæ. Telson concave below, subrectangular, about as broad as long, rounded posteriorly, cleft about half-way down.

Male.-Differs in having the crests on segments of pereion not so prominent; first segment not produced so much along the head; second gnathopod when fully developed chelate, basos long and narrow, ischios and meros short, carpus apparently united with propodos, which is large and produced distally into a fixed finger against which the dactylos impinges, dactylos strong, rather blunt at end ; the ends of both fingers setose. The first pair of gnathopoda same as those of female.

Colour-various, greater part of body usually tinged with red but sometimes with blue, integument thick and more or less opaque.

Length about $\frac{1}{4}$ inch.
Hab. Lyttelton Harbour. On seaweed, usually at roots of Macrocystis.

This species is very peculiar in appearance and presents several points of interest.

The maxillipedes are shown in Pl. II., fig. $2 \%$. Both the basos and ischios bear plates, that of the former ending in two rounded teeth, that of the latter rounded at the end and with its inner edge setose, the meros has its distal portion produced externally in a rounded lobe past the extremity of the carpus, the propodos has its distal and inner margins setose, the setæ on the inner margin being minutely serrate; the dactylos is broad, subtriangular, and nearly free from setæ.

The peculiar chelate character of the second pair of gnathopoda of male appears to be acquired only in fully-developed individuals; in smaller specimens they are subchelate, with the palm transverse, as shown in fig. $2 g$; intermediate forms between this and the fully-developed form shown in fig. $2 f$ are also found. At first sight the carpus appears to be absent; I believe that it is joined on to the propodos, but the evidence of this is not quite satisfactory. The sixth segment of the pleon appears to be absent, unless the part that I have described as the basal portion of the last pair of pleopoda represents the sixth segment itself ; if this be the case, the last pleopod will be represented only by a single rounded joint; in either case it certainly bears the appearance of being rudimentary and useless.

## Genus Montaguana.

(Montagua, Spence Bate, Cat. Amphip. Crust. Brit. Mus., p. 54.)
As the name Montagua was long ago used by Fleming for a genus of Nudibranch Mollusca, I have altered the name of Mr. Spence Bate's genus to Montaguana.

Generic characters :-" The superior antennæ are as long as the inferior, and not furnished with a secondary appendage. The mandibles are not furnished with an appendage. The maxillipedes are pediform, unguiculate, and without, or with only rudimentary, squamiform plates. The first pair of gnathopoda are small, subchelate, the coxæ not developed into a squamiform plate. The second pair of gnathopoda are larger than the first, and have the coxæ very large, squamiform, deeper than the body, and produced anteriorly, so as to cover the organs of the mouth; the propodos is developed upon the same type as in the first pair. The pereiopoda are subequal; the coxæ of the two anterior pairs are very largely developed,
deeper than the body, and produced posteriorly, so as to cover that of the following pair of pereiopoda. The posterior pair of pleopoda are styliform, unibranched, the ramus biarticulate. The telson is simple and squamiform."
Montaguana miersii?
(? Montaguana miersii, Haswell, Proceedings Linn. Soc. N.S.W., vol. iv., p. 323, pl. XXIV., fig. 4, and Cat. Australian Crust., p. 226.)
"Coxæ of the posterior gnathopoda and the two first pairs of pereiopoda much deeper than their respective segments. Superior and inferior antennæ subequal in length, equal in length to the cephalon and first three segments of the pereion ; the peduncles stout, rather shorter than the flagella. Anterior gnathopoda small, the propodos subquadrate, the palm nearly transverse. Posterior gnathopoda with the propodos large, cordiform; the palm oblique, undefined. Pereiopoda subequal, rather stont. Colour yellow with brown markings. Length about $\frac{3}{20}$ in."

Hab. Timaru and Lyttelton Harbour.
Mr. Haswell obtained his specimens at Port Jackson. Mine differ from the description and figures given by him in some small points so that I am rather doubtful whether they are really the same species or not.

The first pair of gnathopoda has the palm more oblique than shown in Mr. Haswell's figure. In the second gnathopoda the specimens obtained at Timaru differ somewhat from those obtained at Lyttelton, though much too close in other respects to be considered as distinct species. The Lyttelton specimens are nearest to those described by Mr. Haswell. The palm, though it can hardly be called defined, yet has two stout setre at the place where the end of the finger reaches to, one on each side; on the under-side of the propodos towards the base are a few rather long setæ, not shown in Mr. Haswell's figure ; and in the centre of the palm is a small sharp projection. In the Timaru specimens the propodos is much stouter, palm less oblique, and without the small projection at its centre.

In the last three pairs of pleopoda my specimens closely resemble those of $M$. longicornis as figured by Mr. Haswell. In the figure of $M$. miersii the last pair of pleopoda are drawn with two rami, but this must, I suppose, be a slip of the artist's.

## Genus Cyproidia, Haswell.

(Proc. Linn. Soc. N.S.W., vol. iv., p. 320, and Cat. Aust. Crust., p. 229.)
"Body broad. Pereion and pleon of equal length. Coxæ of guathopoda very small. Coxæ of the first and second pairs of pereiopoda enormously developed, and cemented together to form broad and deep lateral shields, concealing almost entirely the gnathopoda and pereiopoda, and extending forwards to the sides of the cephalon, and backwards as far as
the posterior border of the sixth segment of the pereion, excavated posteriorly for the shallow coxr of the third pereiopoda. Coxæ of last two pairs of pereiopoda very small. Antennæ subequal superior without an appendage. Nandibles with a pạlp. Naxillipedes mangiculate; both basos and ischium armed with small squamiform plates. Guathopoda subcheliform. Pereiopoda slender. Posterior pleopoda biramous. Telson single." Cyproidia (?) crassa, sp. nov. Pl. III., fig. 1.

Eyes large. All the mouth parts and nearly all the lower antennæ concealed by the coxæ of the two pairs of gnathopoda and the first pair of pereiopoda. Coxæ of first pair of gnathopoda triangular about as deep as its segment, extending anteriorly over the mouth parts, posterior edge slightly curved. Coxa of second guathopod and first pereiopod deeper than their segments, rather narrow, slightly curved. Coxæ of second pair of pereiopoda enormously developed, much deeper than its segment and extending posteriorly as far as the posterior border of the seventh segment of pereion, excavated above, posteriorly for the shallow coxa of the third pereiopod. Coxæ of last two pairs of pereiopoda rudimentary, hidden. The coxæ of the two gnathopoda and the first two pereiopoda united together to form deep broad lateral shields which enclose all but the ends of the pereiopoda. Upper antennæ with first two joints of peduncle stout, subequal, the second produced above into a strong tooth, third joint small and indistinguishable from the flagellum; flagellum nearly as long as peduncle bearing on its under surface long auditory cilia. First joint of peduncle of lower antennæ large, second joint shorter, articulated to the first by a geniculate joint, third joint longer than second but not quite so long as the first followed by a short flagellum about as long as the third joint of peduncle. Two pairs of gnathopoda equal in size and similar in shape, meros and carpus both having the inner distal angle produced into a lobe setose at the end, propodos rather small, hairy, some of the hairs on the palm strong, plumose at tip, dactylos rather small, slightly curved at the tip; the gnathopod appears to be but very imperfectly subchelate. Pereiopoda subequal, setæ few, short. Of the last three pairs of pleopoda the first is the longest, peduncle rather slender, rami slender, lanceolate, nearly equal, almost naked, second similar but with rami more unequal, last stouter, rami unequal, naked. Telson oval, slightly narrower towards the end than at base, margins entire, no setæ. Colour-brown.

Length, about $\frac{1}{7}$ inch.
Hab. Lyttelton harbour.
As will be seen from the figure and the description already given, this species differs very considerably in the form of the coxæ from Mr. Haswell's species for which he made the genus ; it will most probably form the type

TRANS.NZINSTITUTE, VOLXV.PIII.

of a new genus, but, as I have only had two specimens, both of the same species, I prefer to leave it under Mr. Haswell's genus for the present. The details (fig. $1 a-d$ ) were taken from a small specimen, and hence may not represent quite accurately their form in more adult specimens. Genus Moera, Leach. (Cat. Amphip. Crust. Brit. Mus., p. 187.)
Moera spinosa, Haswell. (Proc. Linn. Soc. N.S.W., iv., p. 268, pl. x., fig. 5 ; and Cat. Aust. Crust., p. 257.)
"Posterior margin of the five anterior segments of the pleon armed with a few acute teeth or spines ; fourth and fifth segments armed behind with acute spines. Coxæ much shallower than their respective segments. Lateral plate of the third segment of the pleon serrated posteriorly. Eyes long, oval. Superior antennæ more than lialf the length of the body; first segment of peduncle as long as the cephalon and first segment of the pereion; second rather longer; third very short; flagellum as long as the peduncle ; appendage nearly half as long as the flagellum.*
"Inferior antennæ more than half as long as the superior pair' third segment of peduncle equal in length to the first segment of the pereion ; fourth twice as long as the third, fifth as long as the cephalon; flagellum as long as the fifth segment of the peduncle. Anterior guathopoda hairy, carpus rather longer than the propodos; the latter ovate; palm oblique, notched. Posterior gnathopoda with the propodos large, ovate, more dilated in the male than in the female, palm defined by a strong acute tooth, and armed in the male with two other prominent teeth. Two anterior pairs of pereiopoda sub-equal. Third pair rather shorter than the fourth and fifth; basos of the three posterior pairs produced at its postero-distal angle; meros, carpus, and propodos serrated and hairy. Fifth pair of pleopoda much shorter than the fourth. Sixth pair large, with a stout protopodite and two broad-lanceolate rami, the latter serrated and armed with setæ. Telson double, each half ending in a sharp spine, and armed with a bundle of stiff setæ. Length 8 lines."

Hab. Auckland.
Of this species I have two specimens, a male and a female, for which I have to thank Professor Hutton. He found them in a collection of Mollusca sent him from Auckland. Mr. Haswell's specimens were from Tasmania. In my specimen of the male the second gnathopod of the right side only has the two promiment teeth on the palm, and these are rather larger and more blunt at the end than those shown in Mr. Haswell's figure; the second gnathopod of the left side is like those of the female, having the palm slightly convex, and without the two teeth. (See plate II., fig. 3a.)

[^1]Moera petri i, G. M. Thomson. (Trans. N.Z. Inst., xiv., p. 236, pl. xviii., fig. B).
This species was described by Mr. Thomson from specimens obtained at Port Pegasus in the dredge. I have formd it pretty abundantly in Lyttelton Harbumr at low tide. The female differs from the male in the form of the second pair of gnathopoda. In these the carpus is much longer than in the male, being slightly longer than broad; it is densely haired, the hairs being chiefly arranged in rows ; many if not all these hairs are serrated; the propodos is only very slightly broader than the carpus, having tufts of setre along both sides and also along the middle, those on the under smrface being the most mumerous and the thickest. Palm imperfectly defined by several strong setæ at the point where the tip of the dactylos impinges. Dactylns slender, very acute. (See plate II., fig. 4a.)

In the male my specimens have the propodos of the gnathopoda less hairy than the one diawn by Mr. Thomson, and the dactylos is more blunt, being quite romnded at the end.

The two acute spines on the postero-dorsal margin of the fomth segment of the pleon are iuvariable in both sexes.

> Genus Harmonia, Haswell.
(Proc. Linn. Soc. N.S.IV., vol. iv., p. 330, and Cat. Aust. Crust., p. 250.)
Generic characters:-"Coxæ not so deep as their respective segments. Superior antennæ with an appendage. Inferior antennæ longer than the superior pair. Mandibles with a palp. Maxillipedes unguiculate, subpediform, provided with a squamiform plate on the basos only. Gnathopoda subchelate, unequal, posterior pair very large. Pereiopoda stout. Posterior pleopoda biramous, the rami short, conical. Telson single, elongate."

Of this genus Mr. Haswell says: "This genus, of which I have as yet observed but one species, has affinities with Eurystheus and Amathia, but is distinguished from the former by the form of the telson and the stontness of the pereiopoda, and from the latter mainly by the large size of the posterior gnathopoda."

Before noticing Mr. Haswell's genus I had found the following species, and had begun to describe it as a new species of Eurystheus.
Harmoniu crassipes, Haswell. (l.c., p. 330, pl. xix., fig. 3.)
"Superior antennæ as long as the cephalon and first six segments of the pereion, first and second segments of the peduncle subequal, the second narrower than the first, third scarcely distinguishable from the articuli of the flagellum; flagellum rather longer than the peduncle. Inferior antemæ longer than the superior pair ; peduncle and flagellum subequal. Anterior gnathopoda small; propodos ovoid; palm oblique, undefined. Pusterior gnathopoda much larger than the anterior pair; carpus sub-
